

Chapter II. Elements of Signal Detection Theory

Introduction

- ➤ Signal detection = the problem of deciding which signal is present from 2 or more possibilities
 - one possibility may be that there is no signal
- Based on noisy observations
 - signals are affected by noise
 - noise is additive (added to the original signal)

The context for signal detection

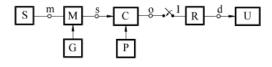

Figure 1: Block scheme of a communication system

- ▶ Block scheme of a communication system:
 - ▶ Information source: generates messages a_n with probabilities $p(a_n)$
 - Generator: generates different signals $s_1(t), \dots s_n(t)$
 - ▶ Modulator: transmits a signal $s_n(t)$ for message a_n
 - Channel: adds random noise
 - Sampler: takes samples from the signal $s_n(t)$
 - \triangleright Receiver: **decides** what message a_n has been transmitted
 - User receives the recovered messages

Problem formulation

- ▶ There are two messages a_0 and a_1 (e.g. logical 0 and 1)
- ▶ Messages are encoded as signals $s_0(t)$ and $s_1(t)$
 - for a_0 : send $s(t) = s_0(t)$
- ▶ The signal is affected by additive white noise n(t)
- Receiver receives noisy signal r(t) = s(t) + n(t)
- ▶ **Decision problem**: based on r(t), decide which signal was received, $s_0(t)$ or $s_1(t)$?

Practical scenarios

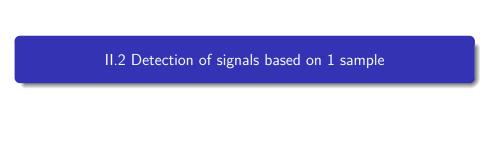

- ▶ Data transmission with various binary modulations:
 - Constant voltage levels (e.g. $s_n(t) = \text{constant} = 0 \text{ or } 5V$)
 - ▶ PSK modulation (Phase Shift Keying): $s_n(t) = \text{cosine with same}$ frequency but various initial phases
 - ► FSK modulation (Frequency Shift Keying): $s_n(t) = \text{cosines with different frequencies}$
 - OFDM modulation (Orthogonal Frequency Division Multiplexing): particular case of FSK
 - ► The receiver gets some noisy signal, has to decide when it is 0 and when it is 1

Practical scenarios

- Radar detections:
 - ▶ a signal is emitted; if there is an obstacle, the signal gets reflected back
 - ▶ the receiver waits for possible reflections of the signal and must **decide**:
 - no reflection is present -> no object
 - reflected signal is present -> object detected

Generalizations

- ▶ Decide between more than two signals
- Number of observations:
 - use only one sample
 - use multiple samples
 - observe the whole continuous signal for some time T

Problem formulation

- ▶ There are two messages a_0 and a_1 (e.g. logical 0 and 1)
- ▶ Messages are encoded as signals $s_0(t)$ and $s_1(t)$
 - ▶ for a_0 : send $s(t) = s_0(t)$ ▶ for a_1 : send $s(t) = s_1(t)$
- ▶ The signal is affected by additive white noise n(t)
- ▶ Receiver receives noisy signal r(t) = s(t) + n(t)
- **Decision problem**: based on r(t), decide which signal was received, $s_0(t)$ or $s_1(t)$?
- Simplest case: receiver **takes just 1 sample** at time t_0 , value is $r = r(t_0)$

Hypotheses and decisions

- ► There are two hypotheses:
 - ▶ H_0 : true signal is $s(t) = s_0(t)$ (a_0 has been transmitted)
 - ▶ H_1 : true signal is $s(t) = s_1(t)$ (a_1 has been transmitted)
- Receiver can take two decisions:
 - ▶ D_0 : receiver decides that signal was $s(t) = s_0(t)$
 - ▶ D_1 : receiver decides that signal was $s(t) = s_1(t)$

Possible outcomes

- There are 4 possible outcomes:
 - 1. **Correct rejection**: true hypothesis is H_0 , decision is D_0
 - Probability is $P_r = P(D_0 \cap H_0)$
 - ► Also known as **True Negative**
 - 2. **False alarm**: true hypothesis is H_0 , decision is D_1
 - Probability is $P_{fa} = P(D_1 \cap H_0)$
 - Also known as False Positive
 - 3. **Miss**: true hypothesis is H_1 , decision is D_0
 - Probability is $P_m = P(D_0 \cap H_1)$
 - Also known as False Negative
 - 4. Correct detection ("hit"): true hypothesis is H_1 , decision D_1
 - Probability is $P_d = P(D_1 \cap H_1)$
 - ► Also known as True Positive

Origin of terms

- ▶ The terms originate from radar applications:
 - ▶ a signal is emitted from source
 - received signal = possible reflection from a target, with lots of noise
 - $ightharpoonup H_0$ = no target is present, no reflected signal (only noise)
 - $ightharpoonup H_1 =$ target is present, there is a reflected signal
 - ▶ hence the names "miss", "hit" etc.

The noise

- In general we consider additive, white, stationary noise
 - additive = the noise is added to the signal
 - white = two samples from the noise are uncorrelated
 - stationary = has same statistical properties at all times
- The noise signal n(t) is unknown
 - ▶ it's random
 - we just know it's distribution, but not the actual values

The sample

▶ The receiver receives:

$$r(t) = s(t) + n(t)$$

- $ightharpoonup s(t) = \text{original signal, either } s_0(t) \text{ or } s_1(t)$
- ightharpoonup n(t) = unknown noise
- ▶ The value of the sample taken at t_0 is:

$$r(t_0)=s(t_0)+n(t_0)$$

- $ightharpoonup s(t_0) = ext{the true signal} = ext{either } s_0(t_0) ext{ or } s_1(t_0)$
- $ightharpoonup n(t_0) = a$ sample from the noise

The sample

- ▶ The sample $n(t_0)$ is a **random variable**
 - since it is a sample of noise (a sample from a random process)
 - ▶ assume is a continuous r.v., i.e. range of possible values is continuous
- $ightharpoonup r(t_0) = s(t_0) + n(t_0) = a \text{ constant} + a \text{ random variable}$
 - it is also a random variable
 - $ightharpoonup s(t_0)$ is a constant, either $s_0(t_0)$ or $s_1(t_0)$
- ▶ What distribution does $r(t_0)$ have?
 - a constant + a r.v. = has same distribution as r.v., but shifted with the constant

The conditional distributions

- Assume the noise has known distribution w(x)
- ▶ The distribution of r = w(x) shifted by $s(t_0)$
- ▶ In hypothesis H_0 , the distribution is $w(r|H_0) = w(x)$ shifted by $s_0(t_0)$
- ▶ In hypothesis H_1 , the distribution is $w(r|H_1) = w(x)$ shifted by $s_1(t_0)$
- $w(r|H_0)$ and $w(r|H_1)$ are known as **conditional distributions** or **likelihood functions**
 - "|" means "conditioned by", "given that"
 - i.e. considering one hypothesis or the other one
 - r is the unknown of the function

The conditional distributions

Example:

A constant signal s(t) can have two values, 0 or 4. The signal is affected by noise $\mathcal{N}(\mu=0,\sigma^2=2)$. What is the distribution of a sample r, in both hypotheses?

Decision problem

The problem of decision:

- ▶ We have two possible distributions (one in each hypothesis)
- ightharpoonup We have a sample $r=r(t_0)$, which could have come from either one
- Which hypothesis do we decide is the correct one?

The likelihood of a parameter

▶ In general, the likelihood of a some parameter P based on some observation O = the probability density of O, if the parameter has value P:

$$L(P|O) = w(O|P)$$

- ► In our case:
 - ▶ the unknown parameter = which hypothesis H is the true one
 - ightharpoonup the observation = the sample r that we got
- ightharpoonup The **likelihood of a hypothesis H** based on the **observation** r is:

$$L(H_0|r) = w(r|H_0)$$

$$L(H_1|r) = w(r|H_1)$$

Maximum Likelihood decision criterion

- Maximum Likelihood (ML) criterion: choose the hypothesis that has the **highest likelihood** of having generated the observed sample value $r = r(t_0)$
 - "pick the most likely hypothesis"
 - "pick the hypothesis with a higher likelihood"

$$\frac{L(H_1|r)}{L(H_0|r)} = \frac{w(r|H_1)}{w(r|H_0)} \underset{H_0}{\overset{H_1}{\geqslant}} 1$$

- lacktriangle We choose the higher value between $w(r(t_0)|H_0)$ and $w(r(t_0)|H_1)$
- This is known as a likelihood ratio test

Example: gaussian noise

Example (follow-up):

- A constant signal s(t) can have two values, 0 or 4. The signal is affected by noise $\mathcal{N}(\mu=0,\sigma^2=2)$.
- ▶ What is the decision taken with the ML criterion, if r = 1.6?
- At blackboard:
 - ▶ plot the two conditional distributions for $w(r|H_0)$, $w(r|H_1)$
 - discuss the decision taken for different values of r
 - discuss the choice of the threshold value T for taking decisions

Example: Trees

From what tree did the leaf fall?

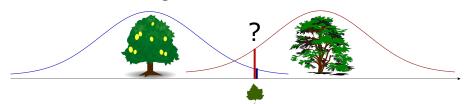

Example: Trees

Pick the tree with the **highest likelihood**:

Gaussian noise (AWGN)

- ▶ Particular case: the noise has normal distribution $\mathcal{N}(0, \sigma^2)$
 - i.e. it is AWGN
- ► Likelihood ratio is $\frac{w(r|H_1)}{w(r|H_0)} = \frac{e^{-\frac{(r-s_1(t_0))^2}{2\sigma^2}}}{e^{-\frac{(r-s_0(t_0))^2}{2\sigma^2}}} \underset{H_0}{\overset{H_1}{\gtrsim}} 1$
- ► For normal distribution, it is easier to apply **natural logarithm** to the terms
 - logarithm is a monotonic increasing function, so it won't change the comparison
 - ▶ if A < B, then log(A) < log(B)

Gaussian noise (AWGN)

Applying natural logarithm to both sides leads to:

$$-(r-s_1(t_0))^2+(r-s_0(t_0))^2 \stackrel{H_1}{\underset{H_0}{\gtrless}} 0$$

Which means

$$|r-s_0(t_0)| \underset{H_0}{\overset{H_1}{\geqslant}} |r-s_1(t_0)|$$

- Note that |r A| =distance from r to A
 - ightharpoonup |r| = distance from r to 0
- So we choose the **smallest distance** between $r(t_0)$ and $s_1(t_0)$ vs $s_0(t_0)$

Maximum Likelihood for gaussian noise

- ML criterion **for gaussian noise**: choose the hypothesis based on whichever of $s_0(t_0)$ or $s_1(t_0)$ is **nearest** to our observed sample $r = r(t_0)$
 - also known as nearest neighbor principle / decision
 - very general principle, encountered in many other scenarios
 - because of this, a receiver using ML is also known as minimum distance receiver

Steps for ML decision

- 1. Sketch the two conditional distributions $w(r|H_0)$ and $w(r|H_1)$
- 2. Find out which function is higher at the observed value $r = r(t_0)$ given.

Steps for ML decision in case of gaussian noise

- Only if the noise is Gaussian, identical for all hypotheses:
 - 1. Find $s_0(t_0)=$ the value of the original signal, in absence of noise, in case of hypothesis H_0
 - 2. Find $s_1(t_0)$ = the value of the original signal, in absence of noise, in case of hypothesis H_1
 - 3. Compare with observed sample $r(t_0)$ and choose **the nearest**

Thresholding based decision

- ► Choosing the nearest value = same thing as **comparing** r **with a** threshold $T = \frac{s_0(t_0) + s_1(t_0)}{2}$
 - ▶ i.e. if the two values are 0 and 5, decide by comparing with 2.5 (like in laboratory)
- ► For the **ML criterion**, the threshold = the **cross-over point** between the conditioned distributions

Exercise

- A signal can have two possible values, 0 or 5. The signal is affected by white gaussian noise \mathcal{N} ($\mu=0,\sigma^2=2$). The receiver takes one sample with value r=2.25.
 - a. Write the expressions of the conditional probabilities and sketch them
 - b. What is the decision based on the Maximum Likelihood criterion?
 - c. What if the signal 0 is affected by gaussian noise $\mathcal{N}(0,0.5)$, while the signal 5 is affected by uniform noise $\mathcal{U}[-4,4]$?
 - d. Repeat b. and c. assuming the value 0 is replaced by -1

Decision regions

- ► The **decision regions** = the range of values of *r* for which a certain decision is taken
- ightharpoonup Decision regions R_0 = all the values of r which lead to decision D_0
- lacktriangle Decision regions $R_1=$ all the values of r which lead to decision D_1
- lacktriangle The decision regions cover the whole ${\mathbb R}$ axis
- Example: indicate the decision regions for the previous exercise:
 - $ightharpoonup R_0 = [-\infty, 2.5]$
 - ► $R_1 = [2.5, \infty]$

The likelihood function

- ► The subtle distinction in terms: "probability" vs "likelihood"
- ▶ Consider the conditional distribution $w(r|H_i)$ in the previous example:

$$\frac{1}{\sigma\sqrt{2\pi}}e^{-\frac{(r-s_i(t_0))^2}{2\sigma^2}}$$

- ▶ Which is the unknown in this function?
 - in general, the unknown is r
 - but for our decision problem it is *i*, and *r* is known

Terminology: probability vs likelihood

- ▶ In the same mathematical expression of a distribution function:
 - if we know the parameters (e.g. μ , σ , H_i), and the unknown is the value (e.g. r, x) we call it **probability density function** (distribution)
 - if we know value (e.g. r, x), and the unknown is some statistical parameter (e.g. μ , σ , i), we call it a **likelihood function**

Generalizations

- ▶ What if the noise has another distribution?
 - Sketch the conditional distributions
 - Locate the given $r = r(t_0)$
 - ▶ ML criterion = choose the highest function $w(r|H_i)$ in that point
- ► The decision regions are defined by the **cross-over points**
 - ▶ There can be more cross-overs, so multiple thresholds

- ▶ What if the noise has a different distribution in hypothesis H_0 than in hypothesis H_1 ?
- ► Same thing:
 - Sketch the conditional distributions
 - ▶ Locate the given $r = r(t_0)$
 - ▶ ML decision = choose **the highest function** $w(r|H_i)$ in that point

- ▶ What if the two signals $s_0(t)$ and $s_1(t)$ are constant / not constant?
- ▶ We don't care about the shape of the signals
- \blacktriangleright All we care about are **the two values at the sample time** t_0 :
 - $ightharpoonup s_0(t_0)$
 - $ightharpoonup s_1(t_0)$

- ▶ What if we have more than two hypotheses?
- Extend to *n* hypotheses
 - ▶ We have *n* possible signals $s_0(t)$, ... $s_{n-1}(t)$
 - We have n different values $s_0(t_0), \ldots s_{n-1}(t_0)$
 - We have *n* conditional distributions $w(r|H_i)$
 - We choose the highest function $w(r|H_i)$ in the point $r = r(t_0)$

- ▶ What if we take more than 1 sample?
- Patience, we'll treat this later as a separate sub-chapter

Multiple separate detection

- ▶ In a binary communications setup, each detection/decision reads 1 bit
- ▶ We have a different detection for the next bit, and so on

Exercise

▶ A signal can have four possible values: -6, -2, 2, 6. Each value lasts for 1 second. The signal is affected by white noise with normal distribution. The receiver takes 1 sample per second. Using ML criterion, decide what signal has been transmitted, if the received samples are:

$$4, 6.6, -5.2, 1.1, 0.3, -1.5, 7, -7, 4.4$$

Conditional probabilities

- ▶ We compute the **conditional probabilities** of the 4 possible outcomes
- Consider the decision regions:
 - $ightharpoonup R_0$: when $r \in R_0$, decision is D_0
 - $ightharpoonup R_1$: when $r \in R_1$, decision is D_1
- ► Conditional probability of correct rejection
 - ightharpoonup = probability to take decision D_0 in the case that hypothesis is H_0
 - ightharpoonup = probability that r is in R_0 computed from the distribution $w(r|H_0)$

$$P(D_0|H_0) = \int_{R_0} w(r|H_0)dx$$

- ► Conditional probability of false alarm
 - ightharpoonup = probability to take decision D_1 in the case that hypothesis is H_0
 - ightharpoonup = probability that r is in R_1 computed from the distribution $w(r|H_0)$

$$P(D_1|H_0) = \int_{R_1} w(r|H_0) dx$$

Conditional probabilities

- Conditional probability of miss
 - ightharpoonup = probability to take decision D_0 in the case that hypothesis is H_1
 - ightharpoonup = probability that r is in R_0 computed from the distribution $w(r|H_1)$

$$P(D_0|H_1) = \int_{R_0} w(r|H_1) dx$$

- Conditional probability of correct rejection
 - ightharpoonup = probability to take decision D_1 in the case that hypothesis is H_1
 - ightharpoonup = probability that r is in R_1 computed from the distribution $w(r|H_1)$

$$P(D_1|H_1) = \int_{R_1} w(r|H_1) dx$$

Conditional probabilities

- Relation between them:
 - $ightharpoonup P(D_0|H_0) + P(D_1|H_0) = 1$ (correct rejection + false alarm)
 - $ightharpoonup P(D_0|H_1) + P(D_1|H_1) = 1 \text{ (miss + correct detection)}$
 - Why? Prove this.

Computing conditional probabilities

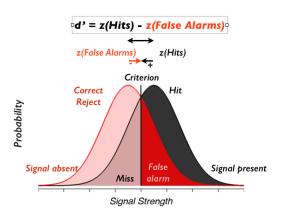

Figure 2: Conditional probabilities

- Ignore the text, just look at the nice colors
- [image from hhttp://gru.stanford.edu/doku.php/tutorials/sdt]*

ML criterion optimality

Theorem:

The ML criterion minimizes the total conditioned probability of error $P(D_1|H_0)+P(D_0|H_1)$

Proof:

Informal: on the previous pivture, if \mathcal{T} is moved either to the right or to the left, the sum of the two areas of false alarm + misses increases.

TODO: rigorous proof

Probabilities of the 4 outcomes

- Conditional probabilities are computed given that one or the other hypothesis is true
- ► They do not account for the probabilities of the hypotheses themselves
 - i.e. $P(H_0) = \text{how many times does } H_0 \text{ happen}$?
 - ▶ $P(H_1)$ = how many times does H_1 happen?
- ▶ To account for these, multiply with $P(H_0)$ or $P(H_1)$
 - $ightharpoonup P(H_0)$ and $P(H_1)$ are known as the **prior** (or **a priori**) probabilities of the hypotheses

Reminder: the Bayes rule

Reminder: the Bayes rule

$$P(A \cap B) = P(B|A) \cdot P(A)$$

- ► Interpretation:
 - ▶ The probability P(A) is taken out from P(B|A)
 - ▶ P(B|A) gives no information on P(A), the chances of A actually happening
 - **Example:** P(score | shoot) = $\frac{1}{2}$. How many goals are scored?
- In our case:

$$P(D_i \cap H_j) = P(D_i|H_j) \cdot P(H_j)$$

 \blacktriangleright for all *i* and *j*, i.e. all 4 cases

Exercise

- ▶ A constant signal can have two possible values, -2 or 5. The signal is affected by gaussian noise $\mathcal{N}(\mu=0,\sigma^2=2)$. The receiver performs ML decision based on a single sample.
 - a. Compute the conditional probability of a false alarm
 - b. Compute the conditional probability of a miss
 - c. If $P(H_0) = \frac{1}{3}$ and $P(H_1) = \frac{2}{3}$, compute the actual probabilities of correct rejection and correct detection (not conditional)

Pitfalls of ML decision criterion

- The ML criterion is based on comparing conditional distributions
 - ightharpoonup conditioned by H_0 or by H_1
- ▶ Conditioning by H_0 and H_1 ignores the prior probabilities of H_0 or H_1
 - Our decision doesn't change if we know that $P(H_0) = 99.99\%$ and $P(H_1) = 0.01\%$, or vice-versa
- ▶ But if $P(H_0) > P(H_1)$, we may want to move the threshold towards H_1 , and vice-versa
 - because it is more likely that the true signal is $s_0(t)$
 - ightharpoonup and thus we want to "encourage" decision D_0
- Looks like we want a more general criterion . . .

Example: Football fields

TODO

Minimum error probability criterion

- ▶ Takes into account the probabilities $P(H_0)$ and $P(H_1)$
- ► The minimum probability of error criterion (MPE):

$$\frac{w(r|H_1)}{w(r|H_0)} \underset{H_0}{\overset{H_1}{\geqslant}} \frac{P(H_0)}{P(H_1)}$$

$$\frac{P(H_1) \cdot w(r|H_1)}{P(H_0) \cdot w(r|H_0)} \underset{H_0}{\overset{H_1}{\geqslant}} 1$$

The minimum error probability criterion

Theorem:

The MPE decision criterion minimizes the total probability of errors:

$$P_e = P_{fa} + P_m = P(D_1 \cap H_0) + P(D_0 \cap H_1)$$

errors = false alarms and misses

Minimum error probability criterion

Proof:

► The probability of false alarm is:

$$P(D_1 \cap H_0) = P(D_1|H_0) \cdot P(H_0)$$

$$= \int_{R_1} w(r|H_0) dx \cdot P(H_0)$$

$$= (1 - \int_{R_0} w(r|H_0 dx) \cdot P(H_0)$$

► The probability of miss is:

$$P(D_0 \cap H_1) = P(D_0|H_1) \cdot P(H_1)$$

= $\int_{R_0} w(r|H_1) dx \cdot P(H_1)$

▶ The total error probability (their sum) is:

$$P_e = P(H_0) + \int_{R_0} [w(r|H_1) \cdot P(H_1) - w(r|H_0) \cdot P(H_0)] dx$$

Minimum probability of error

- ► An integral is always minimal when you integrate the function on all the domain where it is negative
- ▶ The term $w(r|H_1) \cdot P(H_1) w(r|H_0) \cdot P(H_0)$ is negative whenever

$$w(r|H_1) \cdot P(H_1) < w(r|H_0) \cdot P(H_0)$$

i.e. when we take decision D_0 , i.e. on region R_0

- ▶ Therefore the integral on R_0 is minimal,
- $ightharpoonup P(H_0)$ is a constant $=> P_e$ is minimal

Interpretation

- ▶ MPE criterion is more general than ML, depends on probabilities of the two hypotheses
 - ► Also expressed as a likelihood ratio test
- ▶ When one hypothesis has higher probability than the other, the threshold is **pushed in its favor**, towards the other one
- ▶ The ML criterion is a particular case of the MPE criterion, for $P(H_0) = P(H_1) = \frac{1}{2}$

Minimum probability of error - Gaussian noise

Assuming the noise has normal distribution $\mathcal{N}(0, \sigma^2)$

$$w(r|H_1) = e^{-\frac{(r-s_1(t_0))^2}{2\sigma^2}}$$
$$w(r|H_0) = e^{-\frac{(r-s_0(t_0))^2}{2\sigma^2}}$$

Apply natural logarithm

$$-\frac{(r-s_1(t_0))^2}{2\sigma^2} + \frac{(r-s_0(t_0))^2}{2\sigma^2} \underset{H_0}{\overset{H_1}{\geqslant}} \ln \left(\frac{P(H_0)}{P(H_1)} \right)$$

Equivalently

$$(r-s_0(t_0))^2 \stackrel{H_1}{\underset{H_2}{\gtrless}} (r-s_1(t_0))^2 + 2\sigma^2 \cdot \ln\left(\frac{P(H_0)}{P(H_1)}\right)$$

or, after further processing:

$$r \underset{H_0}{\overset{H_1}{\geqslant}} \frac{s_0(t_0) + s_1(t_0)}{2} + \frac{\sigma^2}{s_1(t_0) - s_0(t_0)} \cdot \ln\left(\frac{P(H_0)}{P(H_1)}\right)$$

Interpretation 1: Comparing distance

For ML criterion, we compare the (squared) distances:

$$|r - s_0(t_0)| \stackrel{H_1}{\underset{H_0}{\gtrless}} |r - s_1(t_0)|$$
 $(r - s_0(t_0))^2 \stackrel{H_1}{\underset{H_0}{\gtrless}} (r - s_1(t_0))^2$

For MPE criterion, we compare the squared distances, but a supplementary term appears in favour of the most probable hypothesis:

$$(r-s_0(t_0))^2 \underset{H_0}{\stackrel{H_1}{\geqslant}} (r-s_1(t_0))^2 + 2\sigma^2 \cdot \ln\left(\frac{P(H_0)}{P(H_1)}\right)$$

▶ term depends on the ratio $\frac{P(H_0)}{P(H_1)}$

Interpretation 2: The threshold value

 \triangleright For ML criterion, we compare r with a threshold T

$$r \underset{H_0}{\gtrless} \frac{s_0(t_0) + s_1(t_0)}{2}$$

► For MPE criterion, the threshold is moved towards the less probable hypothesis:

$$r \underset{H_0}{\overset{H_1}{\geqslant}} \frac{s_0(t_0) + s_1(t_0)}{2} + \frac{\sigma^2}{s_1(t_0) - s_0(t_0)} \cdot \ln\left(\frac{P(H_0)}{P(H_1)}\right)$$

• depending on the ratio $\frac{P(H_0)}{P(H_1)}$

Exercises

- Consider the decision between two constant signals: $s_0(t) = -5$ and $s_1(t) = 5$. The signals are affected by gaussian noise $\mathcal{N}(0, \sigma^2 = 3)$ The receiver takes one sample r.
 - a. Find the decision regions R_0 and R_1 according to the MPE criterion
 - b. What are the probabilities of false alarm and of miss?
 - c. Repeat a) and b) considering that $s_1(t)$ is affected by uniform noise $\mathcal{U}[-4,4]$

Minimum risk criterion

- ▶ What if we care more about one type of errors (e.g. false alarms) than other kind (e.g. miss)?
 - ▶ MPE criterion treats all errors the same
 - Need a more general criterion
- ▶ Idea: assign a **cost** to each scenario, minimize average cost
- $ightharpoonup C_{ij} = {\sf cost}$ of decision D_i when true hypothesis was H_j
 - $ightharpoonup C_{00} = \text{cost for good detection } D_0 \text{ in case of } H_0$
 - $ightharpoonup C_{10} = {
 m cost}$ for false alarm (detection D_1 in case of H_0)
 - $ightharpoonup C_{01} = \text{cost for miss (detection } D_0 \text{ in case of } H_1)$
 - $C_{11} = \text{cost for good detection } D_1 \text{ in case of } H_1$
- ► The idea of assigning "costs" and minimizing average cost is very general
 - e.g. IT: Shannon coding: "cost" of each message is the length of its codeword, we want to minimize average cost, i.e. minimize average length

Minimum risk criterion

▶ Define the risk = the average cost value

$$R = C_{00}P(D_0 \cap H_0) + C_{10}P(D_1 \cap H_0) + C_{01}P(D_0 \cap H_1) + C_{11}P(D_1 \cap H_1)$$

- Minimum risk criterion: minimize the risk R
 - i.e. minimize the average cost
 - also known as "minimum cost criterion"

Computations

- ▶ Proof on blackboard: (sorry, no time to put in on slides)
 - ► Use Bayes rule
 - Notations: $w(r|H_i)$ (likelihood)
 - ▶ Probabilities: $\int_{R} w(r|H_i)dV$
- ► Conclusion, decision rule is

$$\frac{w(r|H_1)}{w(r|H_0)} \underset{H_0}{\overset{H_1}{\geqslant}} \frac{(C_{10} - C_{00})p(H_0)}{(C_{01} - C_{11})p(H_1)}$$

Minimum risk criterion

Minimum risk criterion (MR):

$$\frac{w(r|H_1)}{w(r|H_0)} \underset{H_0}{\overset{H_1}{\geqslant}} \frac{(C_{10} - C_{00})p(H_0)}{(C_{01} - C_{11})p(H_1)}$$

Interpretation

- MR is a generalization of MPE criterion (which was itself a generalization of ML)
 - ▶ also expressed as a likelihood ratio test
- ▶ Both **probabilities** and the assigned **costs** can influence the decision towards one hypothesis or the other
- ▶ If $C_{10} C_{00} = C_{01} C_{11}$, MR reduces to MPE:
 - e.g. if $C_{00} = C_{11} = 0$, and $C_{10} = C_{01}$

Minimum Risk - gaussian noise

- ► If the noise is gaussian (normal), do like for the other criteria, apply logarithm
- Obtain:

$$(r-s_0(t_0))^2 \underset{H_0}{\overset{H_1}{\gtrless}} (r-s_1(t_0))^2 + 2\sigma^2 \cdot \ln\left(\frac{(C_{10}-C_{00})p(H_0)}{(C_{01}-C_{11})p(H_1)}\right)$$

or

$$r \underset{\textit{H}_0}{\gtrless} \frac{s_0(t_0) + s_1(t_0)}{2} + \frac{\sigma^2}{s_1(t_0) - s_0(t_0)} \cdot \ln \left(\frac{(\textit{C}_{10} - \textit{C}_{00})\textit{p}(\textit{H}_0)}{(\textit{C}_{01} - \textit{C}_{11})\textit{p}(\textit{H}_1)} \right)$$

Interpretation 1: Comparing distance

► For MPE criterion, we compare the squared distances, but a supplementary term appears in favour of the most probable hypothesis:

$$(r-s_0(t_0))^2 \stackrel{H_1}{\underset{H_0}{\gtrless}} (r-s_1(t_0))^2 + 2\sigma^2 \cdot \ln\left(\frac{P(H_0)}{P(H_1)}\right)$$

- term depends on the ratio $\frac{P(H_0)}{P(H_1)}$
- ► For MR criterion, besides the probabilities we also are influenced by the costs

$$(r-s_0(t_0))^2 \underset{H_0}{\overset{H_1}{\geqslant}} (r-s_1(t_0))^2 + 2\sigma^2 \cdot \ln \left(\frac{(C_{10}-C_{00})p(H_0)}{(C_{01}-C_{11})p(H_1)} \right)$$

Interpretation 2: The threshold value

► For MPE criterion, the threshold is moved towards the less probable hypothesis:

$$r \underset{H_0}{\overset{H_1}{\geqslant}} \frac{s_0(t_0) + s_1(t_0)}{2} + \frac{\sigma^2}{s_1(t_0) - s_0(t_0)} \cdot \ln\left(\frac{P(H_0)}{P(H_1)}\right)$$

- ▶ depending on the ratio $\frac{P(H_0)}{P(H_1)}$
- ► For MR criterion, besides the probabilities we also are influenced by the costs

$$r \underset{H_0}{\overset{H_1}{\geqslant}} \frac{s_0(t_0) + s_1(t_0)}{2} + \frac{\sigma^2}{s_1(t_0) - s_0(t_0)} \cdot \ln\left(\frac{(C_{10} - C_{00})p(H_0)}{(C_{01} - C_{11})p(H_1)}\right)$$

Influence of costs

- ► The MR criterion pushes the decision towards minimizing the high-cost scenarios
- Example: from the equations:
 - \triangleright what happens if cost C_{01} increases, while the others are unchanged?
 - \triangleright what happens if cost C_{10} increases, while the others are unchanged?
 - what happens if both costs C_{01} and C_{10} increase, while the others are unchanged?

Pascal's wager

Reasoning of the French philosopher and mathematician Blaise Pascal (1623–1662):

God is, or God is not. Reason cannot decide between the two alternatives

You must wager (it is not optional)

If you gain, you gain all; if you lose, you lose nothing Wager, then, without hesitation that He is. There is here an infinity of an infinitely happy life to gain, against a finite number of chances of loss. 1

A philosophical example of using the Minimum Risk criterion

General form of ML, MPE and MR criteria

ML, MPE and MR criteria all have the following form

$$\frac{w(r|H_1)}{w(r|H_0)} \underset{H_0}{\overset{H_1}{\geqslant}} K$$

- ightharpoonup for ML: K=1
- ▶ for MPE: $K = \frac{P(H_0)}{P(H_1)}$ ▶ for MR: $K = \frac{(C_{10} C_{00})p(H_0)}{(C_{01} C_{11})p(H_1)}$

General form of ML, MPE and MR criteria

In gaussian noise, all criteria reduce to:

Comparing squared distances:

$$(r-s_0(t_0))^2 \underset{H_0}{\overset{H_1}{\gtrless}} (r-s_1(t_0))^2 + 2\sigma^2 \cdot \ln(K)$$

ightharpoonup Comparing the sample r with a threshold T:

$$r \underset{H_0}{\gtrless} \underbrace{\frac{s_0(t_0) + s_1(t_0)}{2} + \frac{\sigma^2}{s_1(t_0) - s_0(t_0)} \cdot \ln(K)}_{T}$$

Exercise

- A vehicle airbag system detects a crash by evaluating a sensor which provides two values: $s_0(t) = 0$ (no crash) or $s_1(t) = 5$ (crashing)
- ▶ The signal is affected by gaussian noise \mathcal{N} ($\mu = 0, \sigma^2 = 1$).
- ▶ The costs of the scenarios are: $C_{00} = 0$, $C_{01} = 100$, $C_{10} = 10$, $C_{11} = -100$
 - a. Find the decision regions R_0 and R_1 .

Neyman-Pearson criterion

- ▶ An even more general criteria than all the others until now
- ▶ Neyman-Pearson criterion: maximize probability of correct detection $(P(D_1 \cap H_1))$ while keeping probability of false alarms smaller then a limit $(P(D_1 \cap H_0) \leq \lambda)$
 - ▶ Deduce the threshold T from the limit condition $P(D_1 \cap H_0) = \lambda$
- ML, MPE and MR criteria are particular cases of Neyman-Pearson, for particular values of λ

Exercise

- An information source provides two messages with probabilities $p(a_0) = \frac{2}{3}$ and $p(a_1) = \frac{1}{3}$.
- ▶ The messages are encoded as constant signals with values -5 (a_0) and 5 (a_1).
- ▶ The signals are affected by noise with uniform distribution U[-5,5].
- The receiver takes one sample r.
 - a. Find the decision regions according to the Neymar-Pearson criterion, considering $P_{\rm fa} < 10^{-2}$
 - b. What is the probability of correct detection, in this case?

Summary of criteria

- ▶ We have seen decision based on 1 sample r, between 2 signals (mostly)
- ▶ All decisions are based on a likelihood-ratio test

$$\frac{w(r|H_1)}{w(r|H_0)} \underset{H_0}{\overset{H_1}{\geqslant}} K$$

- ▶ Different criteria differ in the chosen value of K (likelihood threshold)
- ▶ Depending on the noise distributions, the real axis is partitioned into regions
 - region R_0 : if r is in here, decide D_0
 - region R_1 : if r is in here, decide D_1
- ▶ For gaussian noise, the boundary of the regions (threshold) is

$$T = \frac{s_0(t_0) + s_1(t_0)}{2} + \frac{\sigma^2}{s_1(t_0) - s_0(t_0)} \cdot \ln(K)$$

Comparing two decision problems

- Suppose we have a decision problem with $s_0(t) = 0$, $s_1(t) = 10$, and noise $\mathcal{N}(\mu = 0, \sigma^2 = 4)$
- Suppose we have another totally different decision problem, with $s_0(t) = 10$, $s_1(t) = 16$, and noise $\mathcal{U}[-8, 8]$
- ▶ Which one is easier? How can we compare them?
- ▶ How to evaluate the overall performance in a decision problem?
 - We need to compare the "good" probabilities (P_{cd}, P_{cr}) and the "bad" probabilities (P_{fa}, P_m)

Receiver Operating Characteristic

- A decision performance is usually represented with "Receiver Operating Characteristic" (ROC) graph
- ▶ It is a graph of $P_d = P(D_1|H_1)$ as a function of $P_{fa} = P(D_1|H_0)$,
 - obtained for different values of the threshold value T
 - ightharpoonup i.e. for every T you get a certain value of P_{fa} and a certain value of P_{d}

Figure 3: Sample ROC curves

Receiver Operating Characteristic

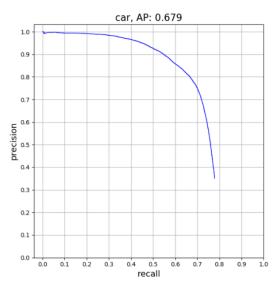

- ROC graph shows there is always a tradeoff between good P_d and bad P_{fa}
 - ightharpoonup to increase P_d one must also increase P_{fa}
 - ▶ if we want to make sure we don't miss any real detections (increase P_d), we pay by increasing the chances of false alarms
- ▶ Different criteria = different likelihood thresholds K = different points on the graph = different tradeoffs
- ▶ An overall performance measure is the total Area Under the Curve (AUC)
 - this doesn't depend on the choice of a particular threshold value
- We can compare two different decision situations (e.g. different signals, or different algorithms etc) by plotting their ROC and comparing their AUC

The Precision-Recall curve

- ▶ A similar curve is the **Precision vs. Recall** curve
- $\blacktriangleright \ \ \mathsf{Precision} = \tfrac{P(D_1 \cap H_1)}{P(D_1 \cap H_1) + P(D_1 \cap H_0)}$
 - ► = True Positives / (True Positives + False Positives)
- ► Recall = $\frac{P(D_1 \cap H_1)}{P(D_1 \cap H_1) + P(D_0 \cap H_1)} = P(D_1 | H_1)$
 - ightharpoonup = True Positives / (True Positives + False Negatives)

Precision-Recall curve

Example of a Precision vs Recall Curve

Precision-Recall curve

Real-life app from which the preceding curve was taken:

Signal-to-Noise Ratio

- ► How to improve the detection performance?
 - ightharpoonup i.e. increase P_D while keeping P_{fa} the same
 - irrespective of what threshold is chosen
- Two solutions:
 - ▶ Increase the seperation between $s_0(t)$ and $s_1(t)$ (increase **signal power**)
 - Reduce the noise (decrease noise power)
 - ▶ i.e. increase Signal-to-Noise ratio

2020-2021 Exam

▶ 2020-2021 Exam: Skip next 3 slides (until Signal-to-noise ratio)

Performance of likelihood-ratio decoding in AWGN

- ► WGN = "White Gaussian Noise"
- Assume equal probabilities $P(H_0) = P(H_1) = \frac{1}{2}$
 - ► Equivalently, consider only the conditional probabilities
- ► All decisions are based on a likelihood-ratio test

$$\frac{w(r|H_1)}{w(r|H_0)} \underset{H_0}{\overset{H_1}{\geqslant}} K$$

► Conditional probability of correct detection is:

$$P_{d} = P(D_{1}|H_{1})$$

$$= \int_{T}^{\infty} w(r|H_{1})$$

$$= (F(\infty) - F(T))$$

$$= \frac{1}{2} \left(1 - erf\left(\frac{T - s_{1}(t_{0})}{\sqrt{2}\sigma}\right) \right)$$

$$= Q\left(\frac{T - s_{1}(t_{0})}{\sqrt{2}\sigma}\right)$$

Performance of likelihood-ratio decoding in AWGN

Conditional probability of false alarm is:

$$\begin{aligned} P_{fa} = & P(D_1|H_0) \\ &= \int_T^\infty w(r|H_0) \\ &= & (F(\infty) - F(T)) \\ &= & \frac{1}{2} \left(1 - erf\left(\frac{T - s_0(t_0)}{\sqrt{2}\sigma}\right) \right) \\ &= & Q\left(\frac{T - s_0(t_0)}{\sqrt{2}\sigma}\right) \end{aligned}$$

- ► Therefore $\frac{T-s_0(t_0)}{\sqrt{2}\sigma} = Q^{-1}(P_{fa})$,
- ► And: $\frac{T s_1(t_0)}{\sqrt{2}\sigma} = Q^{-1}(P_{fa}) + \frac{s_0(t_0) s_1(t_0)}{\sqrt{2}\sigma}$

Performance of likelihood-ratio decoding in AWGN

ightharpoonup Replacing in P_d yields:

$$P_d = Q\left(\underbrace{Q^{-1}(P_{fa})}_{constant} + \frac{s_0(t_0) - s_1(t_0)}{\sqrt{2}\sigma}\right)$$

- Consider a simple case:
 - $ightharpoonup s_0(t_0) = 0$
 - $ightharpoonup s_1(t_0) = A = constant$
- We get:

$$P_d = Q \left(\underbrace{Q^{-1}(P_{fa})}_{constant} - \frac{A}{\sqrt{2}\sigma} \right)$$

Signal-to-noise ratio

- **Signal-to-noise ratio (SNR)** = $\frac{\text{power of original signal}}{\text{power of noise}}$
- Average power of a signal = average squared value = $\overline{X^2}$
 - ▶ Original signal power of s(t) is $\frac{A^2}{2}$
 - Noise power is $\overline{X^2} = \sigma^2$ (when noise mean value $\mu = 0$)
- ► In our case, SNR = $\frac{A^2}{2\sigma^2}$

$$P_d = Q \left(\underbrace{Q^{-1}(P_{fa})}_{constant} - \sqrt{SNR} \right)$$

- ▶ For a fixed P_{fa} , P_d increases with SNR
 - Q is a monotonic decreasing function

Performance depends on SNR

- ► Receiver performance increases with SNR increase
 - high SNR: good performance
 - poor SNR: bad perfomance

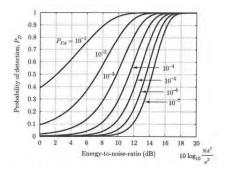

Figure 6: Detection performance depends on SNR

Applications of decision theory

- Can we apply these decision criteria in other engineering problems?
 - e.g. not for deciding between two signals, but for something else
- ▶ The core mathematical problem we solve is:
 - we have 2 (or more) possible distributions
 - we observe 1 value
 - we determine the most likely distribution, according to the value
- In our particular problem, we decide between two signals
- But this can be applied to many other statistical problems:
 - medicine: does this ECG signal look healthy or not?
 - business: will this client buy something or not?
 - ► Typically we use more than 1 value for these, but the mathematical principle is the same

Applications of decision theory

Example (purely imaginary):

- A healthy person of weight = X kg has the concentration of thrombocytes per ml of blood distributed approximately as \mathcal{N} ($\mu = 10 \cdot X, \sigma^2 = 20$).
- ▶ A person suffering from disease D has a much lower value of thrombocytes, distributed approximately as \mathcal{N} (100, $\sigma^2 = 10$).
- ▶ The lab measures your blood and finds your value equal to r = 255. Your weight is 70 kg.
- Decide: are you most likely healthy, or ill?

Multiple samples from a signal

- ▶ The overall context stays the same:
 - ightharpoonup A signal s(t) is transmitted
 - ► There are **two hypotheses**:
 - $ightharpoonup H_0$: true signal is $s(t) = s_0(t)$
 - H_1 : true signal is $s(t) = s_1(t)$
 - Receiver can take two decisions:
 - ▶ D_0 : receiver decides that signal was $s(t) = s_0(t)$
 - ▶ D_1 : receiver decides that signal was $s(t) = s_1(t)$
 - There 4 possible outcomes

Multiple samples from a signal

- ▶ The overall context stays the same:
 - ► There is noise on the channel (unknown)
 - ▶ The receiver receives r(t) = s(t) + n(t)
- ▶ Suppose we take N samples from r(t), not just 1
 - ▶ Each sample is $r_i = r(t_i)$, taken at moment t_i
- ► The samples are arranged in a sample vector

$$\mathbf{r} = [r_1, r_2, ... r_N]$$

Multiple samples from a signal

- ightharpoonup Each sample r_i is a **random variable**
 - ▶ since $r(t_i) = s(t_i) + n(t_i) = a$ constant + a random variable
- ► The sample vector r is a set of N random variables from a random process
- ightharpoonup Considering the whole sample vector ${\bf r}$ as a whole, the values of ${\bf r}$ are described by the **distributions of order** N
- ▶ In hypothesis H_0 :

$$w_N(\mathbf{r}|H_0) = w_N(r_1, r_2, ... r_N|H_0)$$

In hypothesis H_1 :

$$w_N(\mathbf{r}|H_1) = w_N(r_1, r_2, ... r_N|H_1)$$

Likelihood of vector samples

We can apply the same criteria based on likelihood ratio as for 1 sample

$$\frac{w_N(\mathbf{r}|H_1)}{w_N(\mathbf{r}|H_0)} \underset{H_0}{\overset{H_1}{\geqslant}} K$$

- Notes:
 - r is a vector; we consider the likelihood of all the sample vector as a whole
 - $w_N(\mathbf{r}|H_0)$ = likelihood of the whole vector \mathbf{r} being obtained in hypothesis H_0
 - $w_N(\mathbf{r}|H_1) = \text{likelihood of the whole vector } \mathbf{r} \text{ being obtained in hypothesis } H_1$
 - the value of K is given by the actual decision criterion used
- ► Interpretation: we choose the hypothesis that is most likely to have produced the observed data
 - now the data = a set of samples, not just 1

Separation

- Assuming the noise is white noise, the noise samples are independent, and therefore the samples r_i are independent
- In that case the joint distribution $w_N(\mathbf{r}|H_i)$ can be decomposed as a **product of individual distributions**:

$$w_N(\mathbf{r}|H_i) = w(r_1|H_i) \cdot w(r_2|H_i) \cdot ... \cdot w(r_N|H_i)$$

- e.g. the likelihood of obtaining [5.1, 4.7, 4.9] = likelihood of obtaining $5.1 \times$ likelihood of getting $4.7 \times$ likelihood of getting 4.9
- ▶ The $w(r_i|H_i)$ are just conditional distributions for each sample
 - we've seen them already

Separation

▶ Then all likelihood ratio criteria can be written as:

$$\frac{w_N(\mathbf{r}|H_1)}{w_N(\mathbf{r}|H_0)} = \frac{w(r_1|H_1)}{w(r_1|H_0)} \cdot \frac{w(r_2|H_1)}{w(r_2|H_0)} ... \frac{w(r_N|H_1)}{w(r_N|H_0)} \stackrel{H_1}{\underset{H_0}{\gtrless}} K$$

- The likelihood ratio of a vector of samples = product of likelihood ratio for each sample
- We multiply the likelihood ratio of each sample, and then use the same criteria for the end result

Criteria for decisions

► All likelihood ratio criteria can be written as:

$$\frac{w_N(\mathbf{r}|H_1)}{w_N(\mathbf{r}|H_0)} = \frac{w(r_1|H_1)}{w(r_1|H_0)} \cdot \frac{w(r_2|H_1)}{w(r_2|H_0)} ... \frac{w(r_N|H_1)}{w(r_N|H_0)} \overset{H_1}{\underset{H_0}{\gtrless}} K$$

- ▶ The value of *K* is the same as for 1 sample:
 - ▶ for ML: K = 1
 - $\blacktriangleright \text{ for MPE: } K = \frac{P(H_0)}{P(H_1)}$
 - for MR: $K = \frac{(C_{10} C_{00})p(H_0)}{(C_{01} C_{11})p(H_1)}$

Particular case: AWGN

- ► AWGN = "Additive White Gaussian Noise"
- ► In hypothesis H_1 : $w(r_i|H_1) = \frac{1}{\sigma\sqrt{2\pi}}e^{-\frac{(r_i-s_1(t_i))^2}{2\sigma^2}}$
- ► In hypothesis H_0 : $w(r_i|H_0) = \frac{1}{\sigma\sqrt{2\pi}}e^{-\frac{(r_i-s_1(t_i))^2}{2\sigma^2}}$
- Likelihood ratio for vector r

$$\frac{w_N(\mathbf{r}|H_1)}{w_N(\mathbf{r}|H_0)} = \frac{e^{-\frac{\sum (r_i - s_1(t_i))^2}{2\sigma^2}}}{e^{-\frac{\sum (r_i - s_0(t_i))^2}{2\sigma^2}}} = e^{\frac{\sum (r_i - s_0(t_i))^2 - \sum (r_i - s_1(t_i))^2}{2\sigma^2}}$$

Decision criteria for AWGN

 \triangleright The global likelihood ratio is compared with K:

$$\frac{w_N(\mathbf{r}|H_1)}{w_N(\mathbf{r}|H_0)} = e^{\frac{\sum (r_i - s_0(t_i))^2 - \sum (r_i - s_1(t_i))^2}{2\sigma^2}} \underset{H_0}{\overset{H_1}{\gtrless}} K$$

Applying the natural logarithm, this becomes:

$$\sum (r_i - s_0(t_i))^2 \underset{H_0}{\overset{H_1}{\gtrsim}} \sum (r_i - s_1(t_i))^2 + 2\sigma^2 \ln(K)$$

Interpretation 1: geometrical distance

► The sums are squared **geometrical distances**:

$$\sum (r_i - s_1(t_i))^2 = \|\mathbf{r} - \mathbf{s}_1(\mathbf{t})\|^2 = d(\mathbf{r}, s_1(t))^2$$

$$\sum (r_i - s_0(t_i))^2 = ||\mathbf{r} - \mathbf{s_0(t)}||^2 = d(\mathbf{r}, s_0(t))^2$$

- ▶ the distance between the observed samples \mathbf{r} and the true possible underlying signals $s_1(t)$ and $s_0(t)$
- with N samples => distance between vectors of size N
- It comes down to a decision between distances

Interpretation 1: geometrical distance

- Maximum Likelihood criterion:
 - K = 1, ln(K) = 0
 - we choose the **minimum distance** between what is (\mathbf{r}) and what should have been in absence of noise $(s_1(t))$ and $s_0(t)$
 - hence the name "minimum distance receiver"
- Minimum Probability of Error criterion:
 - $K = \frac{P(H_0)}{P(H_1)}$
 - An additional term appears in favor of the most probable hypothesis
- Minimum Risk criterion:
 - $K = \frac{(C_{10} C_{00})p(H_0)}{(C_{01} C_{11})p(H_1)}$
 - Additional term depends on both probabilities and costs

Exercise

Exercise:

- A signal can have two values, 0 (hypothesis H_0) or 6 (hypothesis H_1). The signal is affected by AWGN $\mathcal{N}(0, \sigma^2 = 1)$. The receiver takes 5 samples with values $\{1.1, 4.4, 3.7, 4.1, 3.8\}$.
 - a. What is decision according to Maximum Likelihood criterion?
 - b. What is decision according to Minimum Probability of Error criterion, assuming $P(H_0)=2/3$ and $P(H_1)=1/3$?
 - c. What is the decision according to Minimum Risk Criterion, assuming $P(H_0)=2/3$ and $P(H_1)=1/3$, and $C_{00}=0$, $C_{10}=10$, $C_{01}=20$, $C_{11}=5$?

Another exercise

Another Exercise:

- Consider detecting a signal $s_1(t) = 3\sin(2\pi f_1 t)$ that can be present (hypothesis H_1) or not ($s_0(t) = 0$, hypothesis H_0). The signal is affected by AWGN $\mathcal{N}(0, \sigma^2 = 1)$. The receiver takes 2 samples.
 - a. What are the best sample times t_1 and t_2 to maximize detection performance?
 - b. The receiver takes 2 samples with values $\{1.1, 4.4\}$, at sample times $t_1 = \frac{0.125}{f_1}$ and $t_2 = \frac{0.625}{f_1}$. What is decision according to Maximum Likelihood criterion?
 - c. What if we take the decision with Minimum Probability of Error criterion, assuming $P(H_0)=2/3$ and $P(H_1)=1/3$?
 - d. What is the decision according to Minimum Risk Criterion, assuming $P(H_0)=2/3$ and $P(H_1)=1/3$, and $C_{00}=0$, $C_{10}=10$, $C_{01}=20$, $C_{11}=5$?
 - e. What if the receiver takes an extra third sample at time $t_3 = \frac{0.5}{f_1}$. Will the detection be improved?

Interpretation 2: inner-product

▶ Let's decompose the parentheses in the distances:

$$\sum (r_i - s_0(t_i))^2 \underset{H_0}{\overset{H_1}{\geq}} \sum (r_i - s_1(t_i))^2 + 2\sigma^2 \ln(K)$$

► Equivalent to:

$$\sum (r_i)^2 + \sum s_0(t_i)^2 - 2\sum r_i s_0(t_i) \underset{H_0}{\overset{H_1}{\geqslant}} \sum (r_i)^2 +$$

$$+ \sum s_1(t_i)^2 - 2\sum r_i s_1(t_i) + 2\sigma^2 \ln(K)$$

► Equivalent to:

$$\sum r_i s_1(t_i) - rac{\sum (s_1(t_i))^2}{2} \mathop{\gtrless}_{H_0}^{H_1} \sum r_i s_0(t_i) - rac{\sum (s_0(t_i))^2}{2} + \sigma^2 \ln(K)$$

Interpretation 2: inner-product

Linear algebra: **inner product** of vectors **a** and **b**:

$$\langle a,b\rangle=\sum_i a_ib_i$$

- $ightharpoonup
 ightharpoonup r_i s_1(t_i) = \langle \mathbf{r}, \mathbf{s_1(t)} \rangle$ is the inner product of vector $\mathbf{r} = [r_1, r_2, ... r_N]$ with $\mathbf{s_1(t_i)} = [s_1(t_1), s_1(t_2), ... s_1(t_N)]$
- $\sum_{i} r_i s_0(t_i) = \langle \mathbf{r}, \mathbf{s_0(t)} \rangle$ is the inner product of vector $\mathbf{r} = [r_1, r_2, ... r_N]$ with $\mathbf{s_0(t_i)} = [s_0(t_1), s_0(t_2), ... s_0(t_N)]$
- $\sum (s_1(t_i))^2 = \sum s_1(t_i) \cdot s_1(t_i) = \langle \mathbf{s_1(t)}, \mathbf{s_1(t)} \rangle = E_1$ is the **energy** of vector $s_1(t)$
- $ightharpoonup \sum (s_0(t_i))^2 = \sum s_0(t_i) \cdot s_0(t_i) = \langle \mathbf{s_0(t)}, \mathbf{s_0(t)} \rangle = E_0$ is the **energy** of vector $s_0(t)$

Interpretation 2: inner-product

▶ The decision can be rewritten as:

$$\langle \mathbf{r}, \mathbf{s_1} \rangle - \frac{E_1}{2} \overset{H_1}{\underset{H_0}{\gtrless}} \langle \mathbf{r}, \mathbf{s_0} \rangle - \frac{E_0}{2} + \sigma^2 \ln(K)$$

- Interpretation: we compare the inner-products
 - ▶ also subtract the energies of the signals, for a fair comparison
 - also with a term depending on the criterion

Interpretation 2: inner-product

- Particular case:
 - If the two signals have the same energy: $E_1 = \sum s_1(t_i)^2 = E_0 = \sum s_0(t_i)^2$
 - **Examples**:
 - ▶ BPSK modulation: $s_1 = A\cos(2\pi ft)$, $s_0 = -A\cos(2\pi ft)$
 - ▶ 4-PSK modulation: $s_{n=0,1,2,3} = A\cos(2\pi f t + n\frac{\pi}{4})$
 - ► Then it is simplified as:

$$\langle \mathbf{r}, \mathbf{s_1} \rangle \overset{H_1}{\underset{H_0}{\gtrless}} \langle \mathbf{r}, \mathbf{s_0} \rangle + \sigma^2 \ln(K)$$

Interpretation 2: inner-product

- ▶ Inner-product in signal processing measures similarity of two signals
- ▶ Interpretation: we check if the received samples \mathbf{r} look more similar to $s_1(t)$ or to $s_0(t)$
 - Choose the one which shows more similarity to r
 - ► There is also the subtraction of the energies, for a fair comparison (due to mathematical reasons)
- ▶ Inner product of vectors a and b:

$$\langle a,b\rangle=\sum_i a_ib_i$$

Decision with correlator circuits

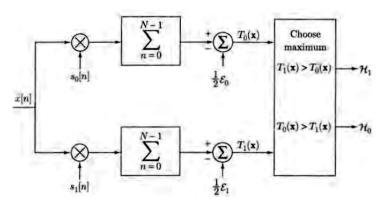

Figure 7: Decision between two signals

[source: Fundamentals of Statistical Signal Processing, Steven Kay]

Example: BPSK

▶ BPSK demodulation:

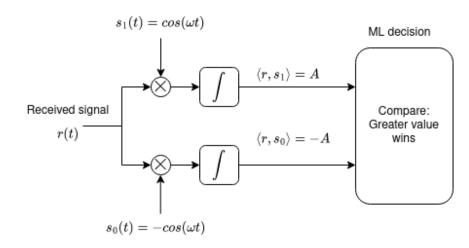

Figure 8: BPSK decision: naive implementation

Example: BPSK

BPSK demodulation:

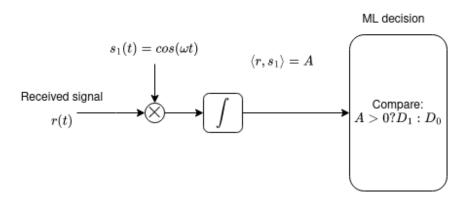

Figure 9: BKSP detection: usual implementation

Example: QPSK

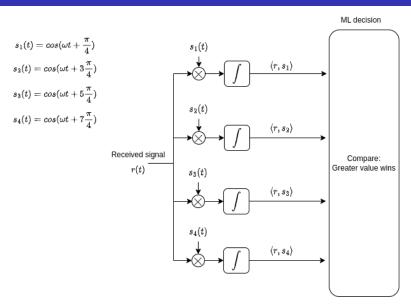

Figure 10: QPSK decision: naive implementation

Example: QPSK

$$\cos(a+b) = \cos(a)\cos(b) - \sin(a)\sin(b)$$

$$s_1(t) = \cos(\omega t + \frac{\pi}{4}) = \frac{\sqrt{2}}{2}\cos(\omega t) + \frac{\sqrt{2}}{2}\sin(\omega t)$$

$$s_2(t) = \cos(\omega t + 3\frac{\pi}{4}) = -\frac{\sqrt{2}}{2}\cos(\omega t) + \frac{\sqrt{2}}{2}\sin(\omega t)$$

$$s_3(t) = \cos(\omega t + 5\frac{\pi}{4}) = -\frac{\sqrt{2}}{2}\cos(\omega t) - \frac{\sqrt{2}}{2}\sin(\omega t)$$

$$s_4(t) = \cos(\omega t + 7\frac{\pi}{4}) = \frac{\sqrt{2}}{2}\cos(\omega t) - \frac{\sqrt{2}}{2}\sin(\omega t)$$

$$s_n(t) = \cos(\omega t + n\frac{\pi}{4}) = A\cos(\omega t) + B\sin(\omega t)$$

$$\text{ML decision}$$

$$\text{Compare: Quadrant of A, B}$$

$$s_2(t) : s_1(t) : s_1(t)$$

$$s_1(t) = \cos(\omega t + n\frac{\pi}{4}) = A\cos(\omega t) + B\sin(\omega t)$$

Figure 11: QKSP detection: usual implementation

▶ How to compute the inner product of two signals r[n] and s[n] of length N?

$$\langle \mathbf{r}, \mathbf{s} \rangle = \sum r_i s(t_i)$$

- Let h[n] be the signal s[n] flipped / mirrored ("oglindit") and delayed with N
 - ightharpoonup starts from time 0, goes up to time N-1, but backwards

$$h[n] = s[N-1-n]$$

- Example:
 - if $s[n] = [\frac{1}{2}, 2, 3, 4, 5, 6]$
 - ► then h[n] = s[N-1-n] = [6, 5, 4, 3, 2, 1]

▶ The convolution of r[n] with h[n] is

$$y[n] = \sum_{k} r[k]h[n-k] = \sum_{k} r[k]s[N-1-n+k]$$

▶ The convolution sampled at the end of the signal, y[N-1] (for n = N-1), is the inner product:

$$y[N-1] = \sum_{k} r[k]s[k]$$

▶ To detect a signal s[n] we can use a **filter with impulse response** = **mirrored version of** s[n], and take the final sample of the output

$$h[n] = s[N-1-n]$$

- it is identical to computing the inner product
- ► Matched filter = a filter designed to have the impulse response the flipped version of a signal we search for
 - ▶ the filter is *matched* to the signal we want to detect
 - rom. "filtru adaptat"

Signal detection with matched filters

- ▶ Use one filter matched to signal $s_1(t_i)$
- ▶ Use another filter matched to signal $s_0(t_i)$
- ightharpoonup Sample both filters at the end of the signal n = N 1
 - obtain the values of the inner products
- Use the decision rule (with the inner products) to decide

Signal detection with matched filters

In case $s_0(t) = 0$, we need only one matched filter for $s_1(t)$, and compare the result to a threshold

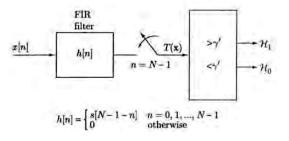

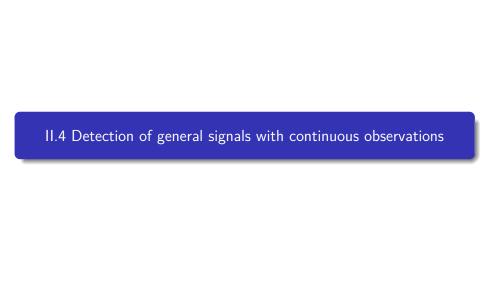

Figure 12: Signal detection with matched filter

[source: Fundamentals of Statistical Signal Processing, Steven Kay]

Continuous observation of a general signal

- ► Continuous observation = we don't take samples anymore, we use **all the continuous signal**
 - ▶ like taking *N* samples but with $N \to \infty$
- ▶ Original signals are $s_0(t)$ and $s_1(t)$
- ► Signals are affected by noise
 - Assume only Gaussian noise, for simplicity
- ightharpoonup Received signal is r(t)

Euclidian space

- ightharpoonup Extend from N samples to the case a full continuous signal
- ► Each signal r(t), $s_1(t)$ or $s_0(t)$ is a data point in an infinite-dimensional Euclidean space
- ▶ **Distance** between two signals is:

$$d(\mathbf{r},\mathbf{s}) = \sqrt{\int (r(t) - s(t))^2 dt}$$

Inner product between two signals is:

$$\langle \mathbf{r}, \mathbf{s} \rangle = \int r(t) s(t) dt$$

▶ Similar with the N dimensional case, but with integral instead of sum

Decision rule for AWGN: distances

For AWGN, same decision rule as always:

$$d(\mathbf{r}, \mathbf{s_0})^2 \underset{H_0}{\overset{H_1}{\geqslant}} d(\mathbf{r}, \mathbf{s_1})^2 + 2\sigma^2 \ln(K)$$

- ▶ Distance = previous formula, with integral
- Same criteria:
 - Maximum Likelihood criterion: K = 1, ln(K) = 0
 - we choose the minimum distance
 - ▶ Minimum Probability of Error criterion: $K = \frac{P(H_0)}{P(H_1)}$
 - ► Minimum Risk criterion: $K = \frac{(C_{10} C_{00})p(H_0)}{(C_{01} C_{11})p(H_1)}$

Decision rule for AWGN: inner products

For AWGN, same decision rule as always:

$$\langle \mathbf{r}, \mathbf{s_1} \rangle - \frac{E_1}{2} \overset{H_1}{\underset{H_0}{\gtrless}} \langle \mathbf{r}, \mathbf{s_0} \rangle - \frac{E_0}{2} + \sigma^2 \ln(K)$$

- ▶ Inner product = previous formula, with integral
- ► All interpretations remain the same
 - we only change the **type of signal** we work with

- Inner product of signals can be computed with matched filters
- ► Matched filter = a filter designed to have the impulse response the flipped version of a signal we search for
 - ightharpoonup if original signal s(t) has length T
 - ▶ then h(t) = s(T t)
 - filter is analogical, impulse response is continuous
- ▶ Output of a matched filter at time t = T is equal to the inner product of the input r(t) with s(t)

Signal detection with matched filters

- ▶ Use one filter matched to signal $s_1(t)$
- Use another filter matched to signal $s_0(t)$
- ightharpoonup Sample both filters at the end of the signal t = T
 - obtain the values of the inner products
- Use the decision rule (with the inner products) to decide

- Review of Euclidean vector spaces
- Vector space
 - ▶ one thing + another thing = still in same space
 - constant × a vector = still in same space
 - has basic arithmetic: sum, multiplication by a constant
 - Examples:
 - ▶ 1D = a line
 - ▶ 2D = a plane
 - ▶ 3D = a 3-D space
 - ► N-D = . . .
 - \triangleright ∞ -D = ..

- ► The fundamental function: **inner product**
 - for discrete signals

$$\langle \mathbf{x}, \mathbf{y} \rangle = \sum_{i} x_{i} y_{i}$$

for continuous signals

$$\langle \mathbf{x}, \mathbf{y} \rangle = \int x(t)y(t)$$

Norm (length) of a vector = sqrt(inner product with itself)

$$\|\mathbf{x}\| = \sqrt{\langle \mathbf{x}, \mathbf{x} \rangle}$$

▶ Distance between two vectors = norm of their difference

$$d(\mathbf{x}, \mathbf{y}) = \|\mathbf{x} - \mathbf{y}\|$$

► Energy of a signal = squared norm

$$E_x = \|\mathbf{x}\|^2 = \langle \mathbf{x}, \mathbf{x} \rangle$$

► Angle between two vectors

$$cos(\alpha) = \frac{\langle x, y \rangle}{||x|| \cdot ||y||}$$

- value between -1 and 1
- if $\langle x, y \rangle = 0$, the two vectors are **orthogonal** (perpendicular)

▶ Bonus: the Fourier transform = inner product with $e^{j\omega t}$

$$\mathcal{F}\{x(t)\} = \langle x(t), e^{j\omega t} \rangle = \int x(t)e^{-j\omega t}$$

 \blacktriangleright for complex signals, the second function is conjugated, hence -j instead of j

$$\langle \mathbf{x}, \mathbf{y} \rangle = \sum_{i} x_{i} y_{i}^{*}$$

 $\langle \mathbf{x}, \mathbf{y} \rangle = \int x(t) y(t)^{*}$

Also same for discrete signals

- ► Conclusion: expressing algorithms in a generic way, with inner products / distances / norms, is very powerful
 - they automatically apply to all vector spaces
 - work once, reuse in many places

II.5 Decision with unknown distributions

Knowing vs not knowing the distribution

- Until now, we always knew what samples we expect
 - ► We knew the signals:

 - $ightharpoonup s_1(t) = ...$
 - We knew the noise type
 - paussian, uniform, etc.
 - ► So we knew the sample distributions:
 - $w(r|H_0) = ...$
 - $w(r|H_1) = ...$
- In real life, things are more complicated

Typical example

- ▶ What if the signals $s_0(t)$ and $s_1(t)$ do not exist / we do not know them?
- Example: face recognition
 - ► Task: identify person A vs B based on a face image
 - ► We have:
 - ▶ 100 images of person A, in various conditions
 - ▶ 100 images of person B, in various conditions

Samples vs distributions

- Compare face recognition with our previous signal detection
- ▶ We still have:
 - ightharpoonup two hypotheses H_0 (person A) and H_1 (person B)
 - ightharpoonup a sample vector $m {f r}=$ the test image we need to decide upon
 - we can take two decisions
 - ▶ 4 scenarios: correct rejection, false alarm, miss, correct detection
- ▶ What's different? We don't have formulas
 - lacktriangle there is no "true" data described by formulas $s_0(t)=...$ and $s_1(t)...$
 - ► (faces of persons A and B are not signals)
 - instead, we have lots of examples of each distribution
 - ▶ 100 images of A = examples of **r** might look in hypotesis H_0
 - ▶ 100 images of B = examples of **r** might look in hypotesis H_1

Machine learning terminology

- Terminology used in machine learning:
 - ► This kind of problem = signal **classification** problem
 - piven one data vector, specify which class it belongs to
 - ▶ The **classes** = the two categories, hypotheses H_i , persons A/B etc
 - ► A training set = a set of known data
 - e.g. our 100 images of each person
 - it will be used in the decision process
 - ► Signal **label** = the class of a signal

Samples vs distributions

- ► The training set gives us the same information as the conditional distributions $w(r|H_0)$ and $w(r|H_1)$
 - \blacktriangleright $w(r|H_0)$ tells us how r looks like in hypothesis H_0
 - \triangleright $w(r|H_1)$ tells us how r looks like in hypothesis H_1
 - the training set shows the same thing, without formulas, but via many examples
- OK, so how to classify the data in these conditions?

The k-NN algorithm

The k-Neareast Neighbours algorithm (k-NN)

- ► Input:
 - ▶ a labelled training set of vectors $\mathbf{x}_1...\mathbf{x}_N$, from L possible classes $C_1...C_L$
 - ▶ a test vector **r** we need to classify
 - a parameter k
- 1. Compute distance from \mathbf{r} to each training vector \mathbf{x}_i
 - can use same Euclidean distance we used for signal detection with multiple samples
- 2. Choose the closest k vectors to \mathbf{r} (the k nearest neighbours)
- 3. Determine class of $\mathbf{r} =$ the majority class among the k nearest neighbours
- Output: the class of r

The k-NN algorithm

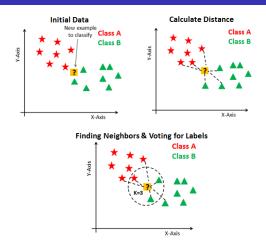

Figure 13: The k-NN algorithm illustrated [1]

[1] image from "KNN Classification using Scikit-learn", Avinash Navlani,

https://www.datacamp.com/community/tutorials/k-nearest-neighbor-classification-scikit-learnger (a) and the community of the

k-NN and MPE decision

- ► If the training set is very large, the k-NN algorithm becomes similar to MPE decision
- ► The number of samples of a class in the vicinity of our point is proportional to $w(r|H_i)P(H_i)$
- ▶ More neighbors of class A than B \Leftrightarrow $w(r|H_A)P(H_A) > w(r|H_B)P(H_B)$

k-NN and MPE decision

► Example: leaves and trees

Exercise

Exercise

- 1. Consider the k-NN algorithm with the following training set, composed of 5 vectors of class A and another 5 vectors from class B:
 - Class A:

$$\mathbf{v}_1 = \begin{bmatrix} 1 \\ -2 \end{bmatrix} \ \mathbf{v}_2 = \begin{bmatrix} -1 \\ 1 \end{bmatrix} \ \mathbf{v}_3 = \begin{bmatrix} -4 \\ 2 \end{bmatrix} \ \mathbf{v}_4 = \begin{bmatrix} 2 \\ 1 \end{bmatrix} \ \mathbf{v}_5 = \begin{bmatrix} -2 \\ -2 \end{bmatrix}$$

Class B:

$$\mathbf{v}_6 = \begin{bmatrix} 7 \\ 0 \end{bmatrix} \ \mathbf{v}_7 = \begin{bmatrix} 2 \\ 3 \end{bmatrix} \ \mathbf{v}_8 = \begin{bmatrix} 3 \\ 2 \end{bmatrix} \ \mathbf{v}_9 = \begin{bmatrix} -3 \\ 8 \end{bmatrix} \ \mathbf{v}_{10} = \begin{bmatrix} -2 \\ 5 \end{bmatrix}$$

Compute the class of the vector $\mathbf{x} = \begin{bmatrix} -3 \\ 6 \end{bmatrix}$ using the k-NN algorithm, with $k=1,\ k=3,\ k=5,\ k=7$ and k=9

Discussion

- k-NN is a supervised learning algorithm
 - training data needs to be labelled
- ► Effect of *k* is to smooth the decision boundary:
 - ► small *k*: lots of edges
 - ► large k: smooth boundary
- \blacktriangleright How to find k?

Cross-validation

- ► How to find a good value for *k*?
 - by trial and error ("băbește")
- ► Cross-validation = use a small testing set for checking what parameter value is best
 - this data set is known as cross-validation set
 - use k = 1, test with cross-validation set and see how many vectors are classified correctly
 - repeat for k = 2, 3, ...max
 - choose value of k with best results on the cross-validation set

Evaluating algorithms

- ► How to evaluate the performance of k-NN?
 - Use a testing set to test the algorithm, check the percentage of correct classification
- ▶ Final testing set should be different from the cross-validation set
 - ► For final testing, use data that the algorithm has never seen, for fairness
- How to split the data into datasets?

Datasets

- Suppose you have 200 face images, 100 images of person A and 100 of person B
- Split the data into:
 - ► Training set
 - data that shall be used by the algorithm
 - ▶ largest part (about 60% of the whole data)
 - ▶ i.e. 60 images of person A and 60 images of B
 - Cross-validation set
 - ightharpoonup used to test the algorithm and choose best value of parameters (k)
 - smaller, about 20%, e.g. 20 images of A and 20 images of B
 - Testing set
 - used to evaluate the final algorithm, with all parameters set to a final value
 - ▶ smaller, about 20%, e.g. 20 images of A and 20 images of B

- k-Means: an algorithm for data clustering
 - identifying groups of close vectors in data
- ▶ Is an example of unsupervised learning algorithm
 - "unsupervised learning" = we don't know the data classes of the signals beforehand

The k-Means algorithm

- ► Input:
 - unlabelled training set of vectors x₁...x_N
 - number of classes C
- ▶ Initialization: randomly initialize the C centroids

$$\mathbf{c}_i \leftarrow \text{ random values}$$

- Repeat
 - 1. Classification: assign each data \mathbf{x} to the nearest centroid \mathbf{c}_i :

$$I_n = \arg\min_i d(\mathbf{x}, \mathbf{c}_i), \forall \mathbf{x}$$

2. Update: update each centroids \mathbf{c}_i = average of the \mathbf{x} assigned to \mathbf{c}_i

$$\mathbf{c}_i \leftarrow \text{ average of } \mathbf{x}, \forall \mathbf{x} \text{ in class } i$$

ightharpoonup Output: return the centroids \mathbf{c}_i , the labels l_i of the input data \mathbf{x}_i

Video explanations of the k-Means algorithm:

- Watch this, starting from time 6:28 to 7:08 https: // www.youtube.com/watch?v=4b5d3muPQmA
- ▶ Watch this, starting from time 3:05 to end https: // www.youtube.com/watch?v=luRb3y8qKX4

- Not guaranteed that k-Means identifies good clusters
 - results depend on the random initialization of centroids
 - repeat many times, choose best result
 - smart initializations are possible (k-Means++)

Exercise

Exercise

1. Consider the following data

$$\{\boldsymbol{v_n}\} = [1.3, -0.1, 0.5, 4.7, 5.1, 5.8, 0.4, 4.8, -0.7, 4.9]$$

Use the k-Means algorithm to find the two centroids ${\bf c}_1$ and ${\bf c}_2$, starting from two random values ${\bf c}_1=-0.5$ and ${\bf c}_2=0.9$. Perform 5 iterations of the algorithm.
